Terminal velocity, steady speed achieved by an object freely falling through a gas or liquid. A typical terminal velocity for a parachutist who delays opening the chute is about 150 miles (240 kilometres) per hour. Raindrops fall at a much lower terminal velocity, and a mist of tiny oil droplets settles at an exceedingly small terminal velocity.

related concepts that tend to get confusing because they depend on whether or not a body is in empty space or in a fluid (e.g., an atmosphere or even water). Take a look at the definitions and equations of the terms, how they are related, and how fast a body falls in free fall or at terminal velocity under different conditions.

Terminal velocity - Forces, acceleration and Newton's laws ...

Terminal velocity is the maximum velocity attainable by an object as it falls through a fluid (air is the most common example). It occurs when the sum of the drag force (F d) and the buoyancy is equal to the downward force of gravity (F G) acting on the object. Since the net force on the object is zero, the object has zero acceleration. In fluid dynamics, an object is moving at its terminal ...

Terminal velocity - Wikipedia
Depends what value you are given for terminal
velocity, generally it`s about 200 km/h or
56m/s but that can vary a lot depending on
your posture and body size, a pro sky diver
can reach 200 miles per hour. "terminal
velocity" is dependent on so many factors,
unless you have a number it pretty much means
nothing. if we take 56m/s, it takes 5.71

Terminal | SLHARPERPOETRY Terminal Velocity is a 1994 American action film directed by Deran Sarafian, written by David Twohy, and starring Charlie Sheen, Nastassja Kinski, James Gandolfini, and Christopher McDonald. It follows a daredevil skydiver (Sheen) who is caught up in a criminal plot by Russian mobsters (Gandolfini and McDonald), forcing him to team up with a freelance secret agent (Kinski) in order to survive.

Terminal Velocity (film) - Wikipedia This means a skydiver with a mass of 75 kg achieves a terminal velocity of about 350 km/h while traveling in a pike (head first) position, minimizing the area and his drag. In a spread-eagle position, that terminal velocity may decrease to about 200 km/h as the area increases. This terminal velocity becomes much smaller after the parachute opens.
